

Searched the web

Yes — that's exactly what that field is for.

When you define a SQL expression as a **Filter** in the knowledge store, there's an **Instructions field** separate from the Name and Code fields. That's where you tell Genie *what the filter is for and when/how to use it* — in plain language.

So the three parts of a filter definition work together like this:

- **Name** — what you call it (e.g., `active_accounts`)
- **Code** — the actual SQL boolean condition (e.g., `status = 'Active' AND churn_date IS NULL`)
- **Instructions** — the natural-language guidance telling Genie the *purpose and usage conditions*, e.g. "Apply this filter whenever the user asks for 'Active Accounts'"

Databricks

That instructions text is what helps Genie decide *when* to actually invoke your filter logic rather than trying to reconstruct the condition itself from scratch. Filling it in is a best practice — it's the mechanism that connects a user's natural-language phrasing ("active customers," "churned accounts," etc.) to the precise SQL you've already written, rather than leaving Genie to guess.
